# Outline

- Current State
- Desirable Properties
- Our Contributions
- Protocols and Security Analysis
- System Implementation
- Discussion

# Introduction

- Password only systems
- Two Factor Authentication TFA
- Online guessing attack
- Offline dictionary attack
  - Many real-world instances
  - Password re-use

**More than 200,000 of these passwords have reportedly been cracked so far.**

# Current State

$|D| = 2^d =$  Size of a password dictionary  
 $t = |z| =$  bandwidth of Device to Client channel  
 $x =$  time

# Desirable Goals

---

## **In case of:**

## **Desired:**

On-line guessing

Probability of  $(1/|D| \times 1/2^t)$  instead of  $1/|D|$

Offline Dictionary attack

Complexity of  $O(|D| \times 2^t)$  instead of  $O(|D|)$

Lunch time attack/  
C-D communication

Shouldn't affect above

Adversary breaks into the  
user's device

security degrades to password-only

Adversary learns the user's  
password

security degrades to the device-only

# Our Contributions

- Novel TFA Protocols to achieve desired TFA properties and Improve security of TFA Schemes.
- Mix-Bandwidth Device TFA Mechanisms to improve ODA resistance by increasing bandwidth  $t$ .

# The Main Idea

- Server stores a hash of the password and a secret  $s$ ,  $h=H(p,s)$
- Device stores the secret  $s$
- Authentication decision based on whether user provides the correct password and owns the device which stores  $s$

# Protocols

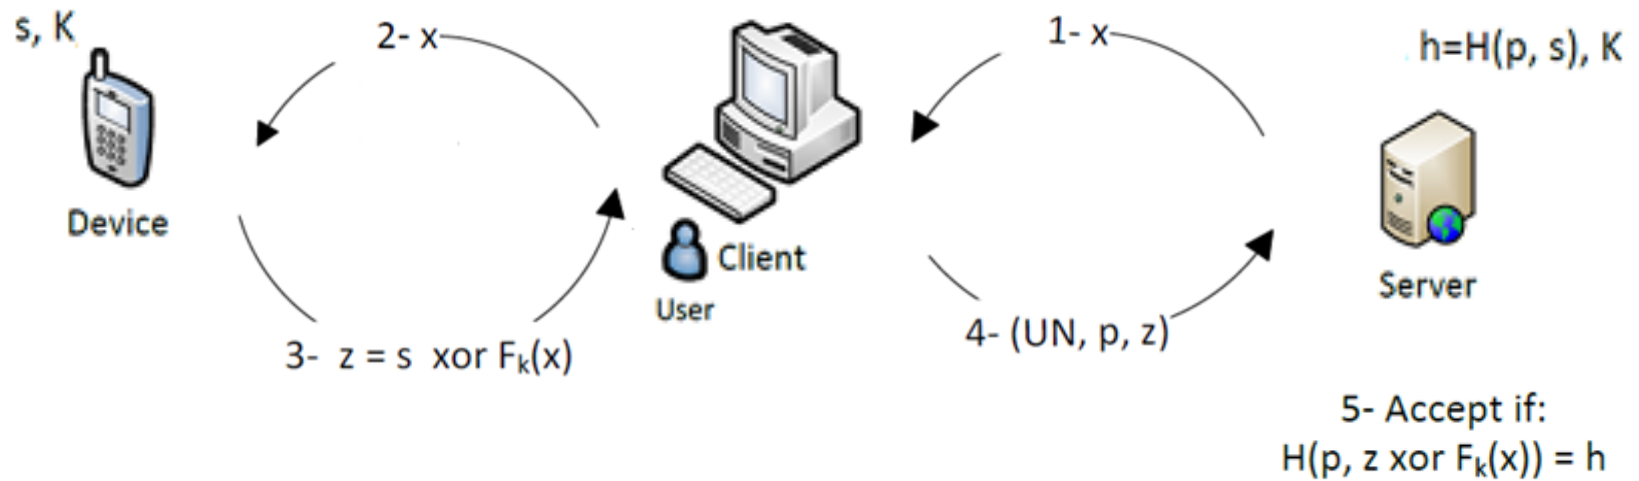

- Time-based TFA protocol
  - Applicable to all device types (Low, Mid, High Bandwidth)
  - Rely on a clock synchronized with the server
- Challenge-Response TFA Protocols
  - Symmetric-key and public-key TFA protocols
  - Applicable for devices that receive a challenge and show PIN

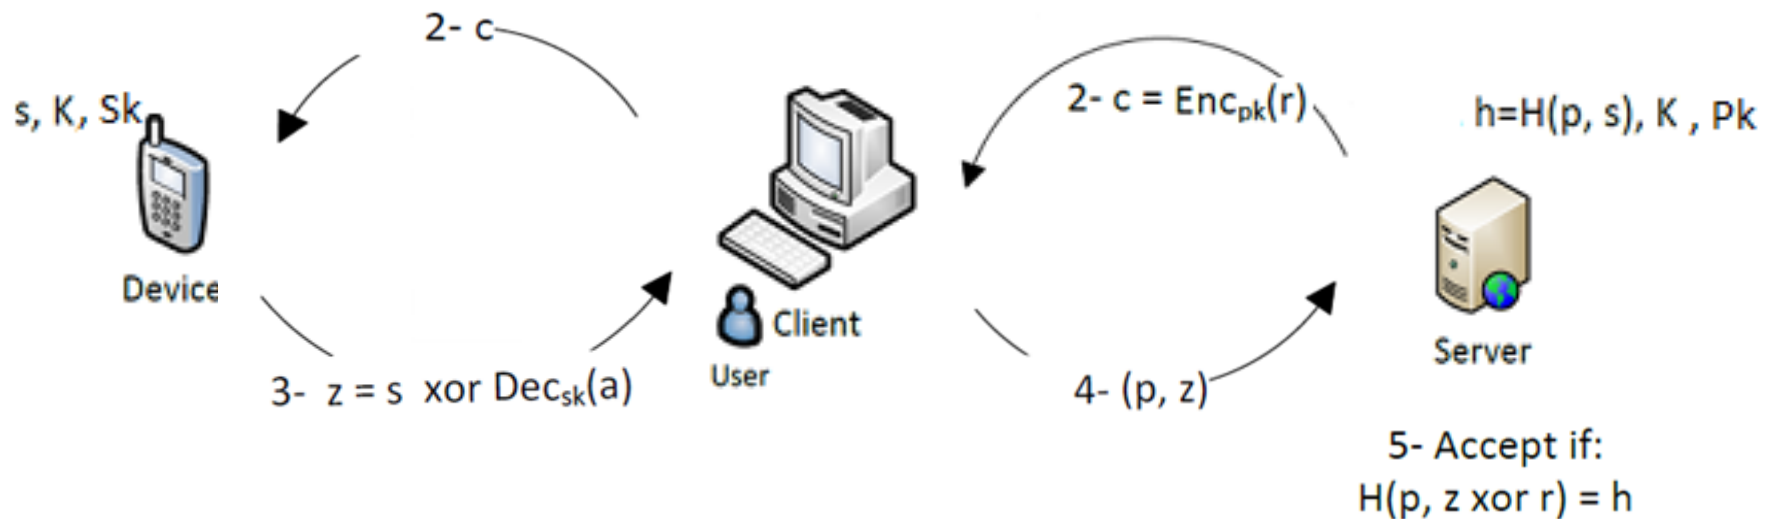

# Time-Based TFA Protocol

# Symmetric-Key TFA Protocol

# Public-Key TFA Protocol

# Security of the Protocols

## In case of:

## Desired:

On-line guessing

Probability of  $(1/|D| \times 1/2^t)$  instead of  $1/|D|$

Offline Dictionary attack

Complexity of  $O(|D| \times 2^t)$  instead of  $O(|D|)$

Lunch time attack/  
C-D communication

Shouldn't affect above

Adversary breaks into the  
user's device

security degrades to password-only

Adversary learns the user's  
password

security degrades to the device-only

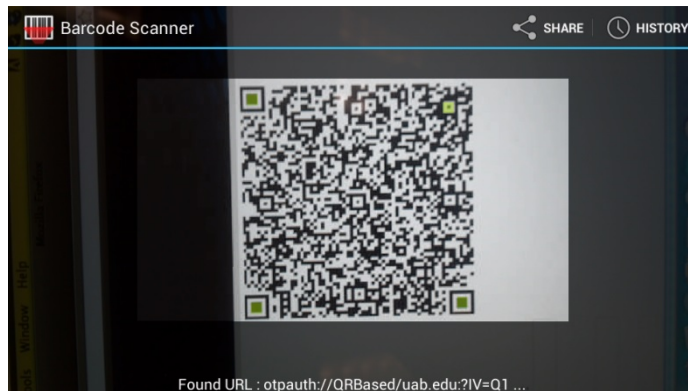

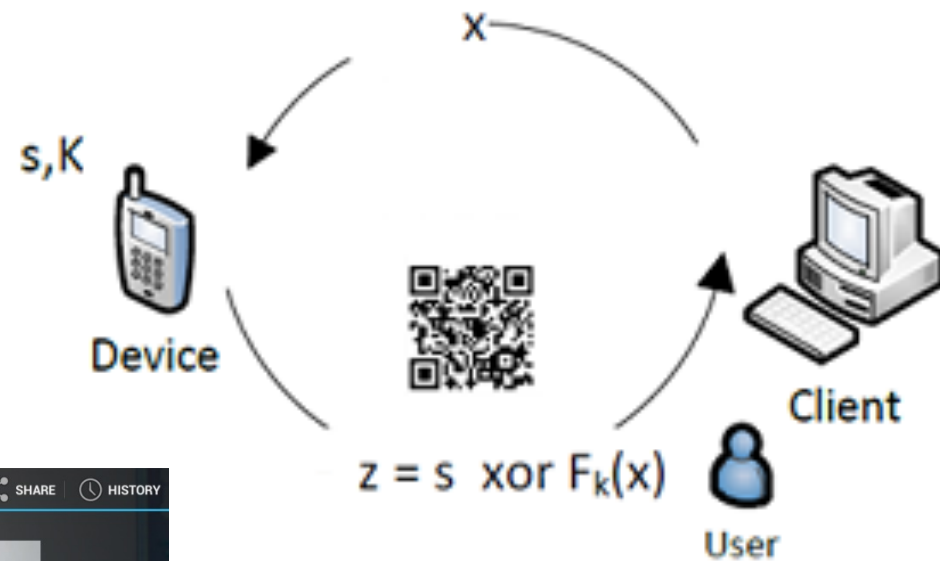

# Notes on System Design and Implementation

- Total 13 TFA mechanisms categorized based on:
  - The underlying protocol
  - The underlying device type
  - The underlying Device - Client channel – PIN, QR, BT, WiFi
    - PIN: 6 digits, manual entry
    - QR: The QR code encoding and decoding ZXing library, HTML5 Server codes and a plain browser on the Client
    - BT: Android application listening on a RFCOMM socket, Client runs a browser extension (Bluetooth API)
    - WF: Virtual WiFi between Client and Device, Client runs a browser extension (chrome.socket API)

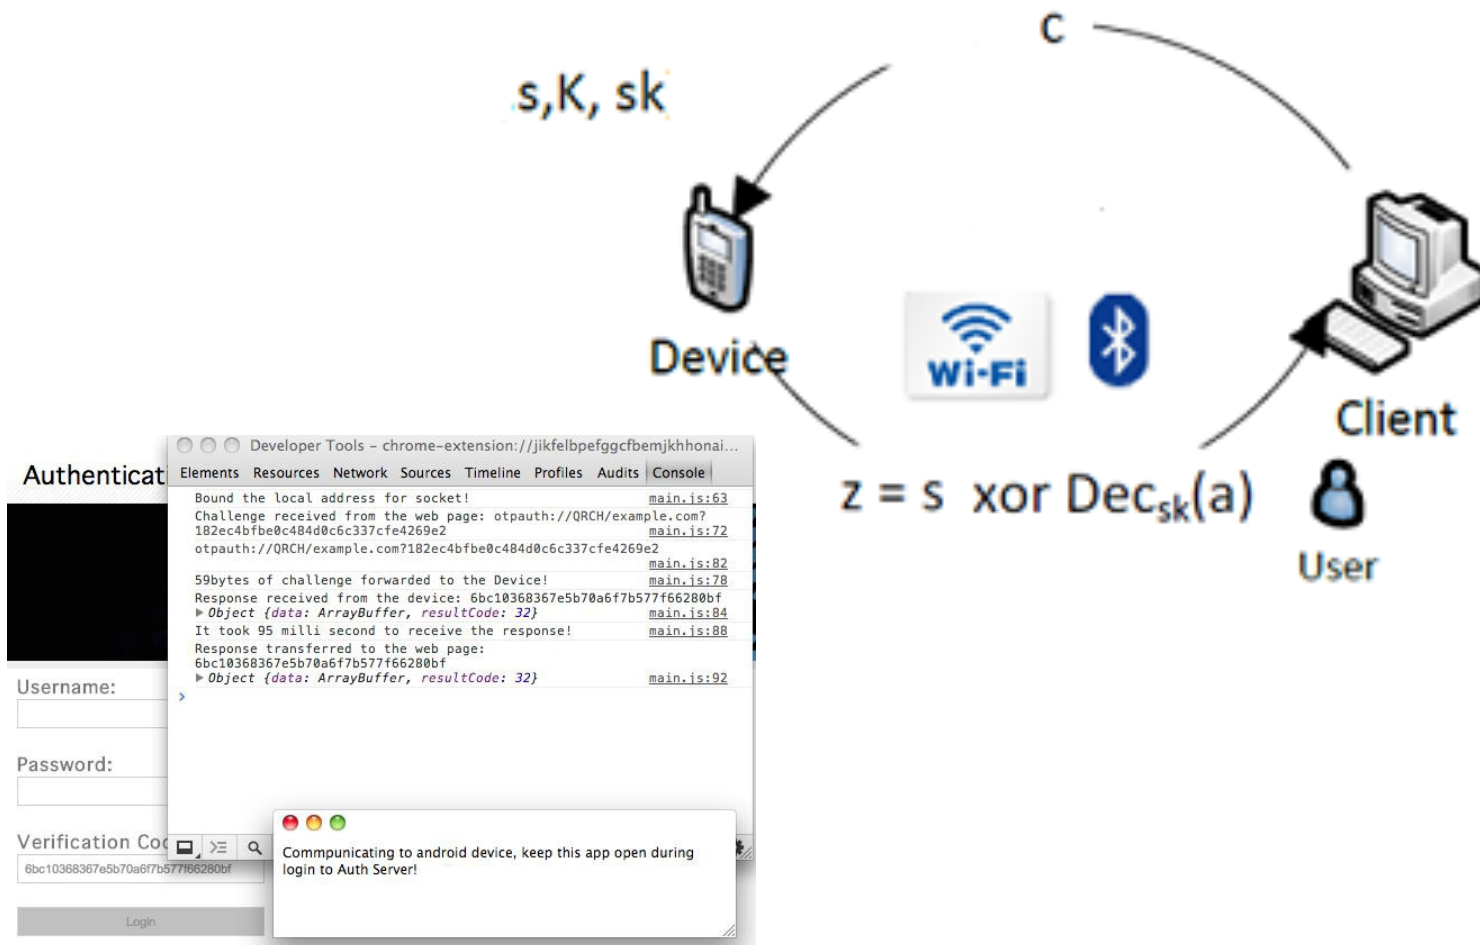

# LBD Authentication Phase

# MBD Authentication Phase

# FBD Authentication Phase

# Discussion and Conclusion

- **Security:**
  - All mechanism provide improved resilience to offline dictionary attacks and online attacks.
  - Challenge-Response protocols are secure against a lunch-time attacker.
  - FBD mechanisms are more secure against online attacks.
- **Usability:**
  - There is no time synchronization requirement in Challenge Response mechanisms.
  - In high bandwidth channels user does not need to manually transfer the PIN.
- **Deployability:**
  - Traditional and LBD work with a plain browser and no special hardware.

Thank you!
